

# Fast UAV Trajectory Generation using Bilevel Optimization

Weidong Sun\*, Gao Tang\*, and Kris Hauser

Presented by Yifan Zhu

Duke University

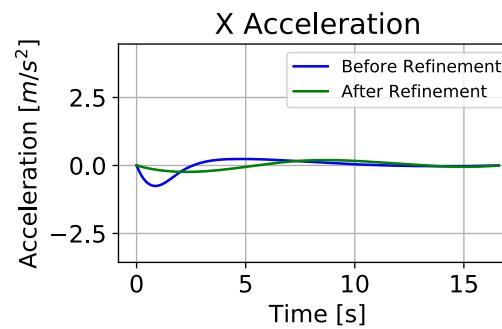

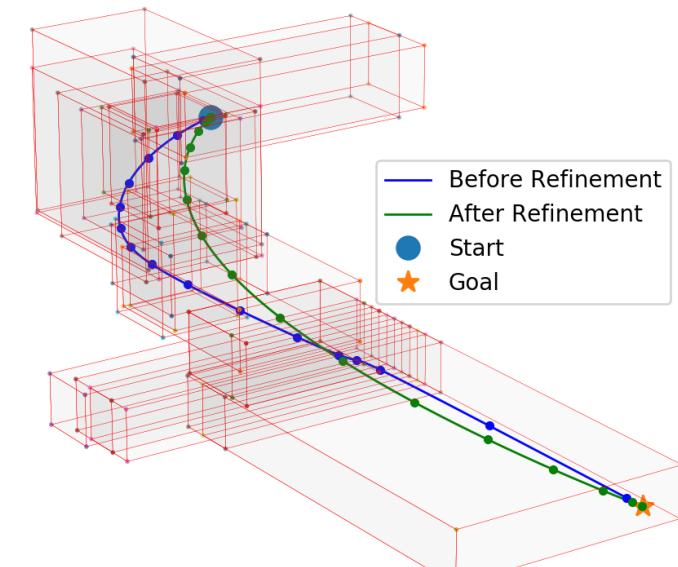

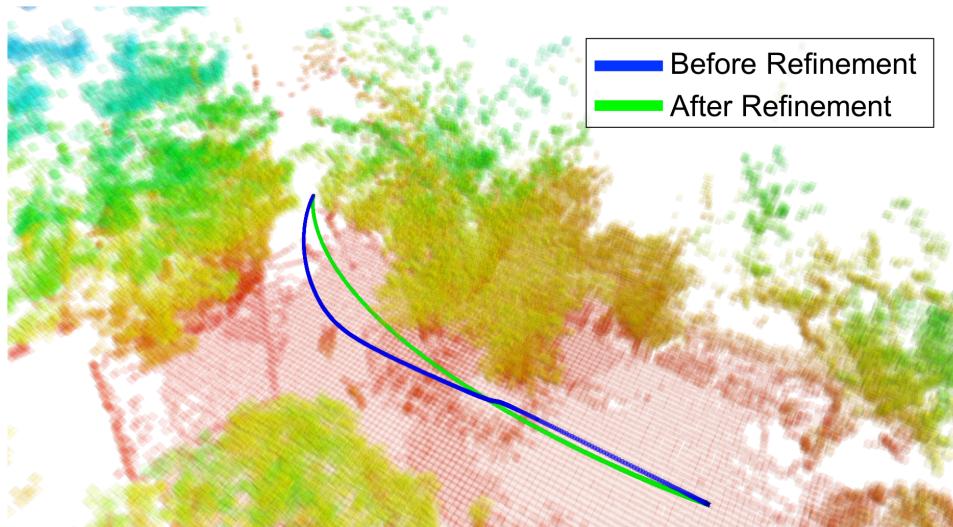

\*Equal Contribution

# Motivation

- Time allocation for spline trajectories is important, but hard

	Jerk	Length
Before <sup>[1]</sup>	45.06	20.7m
After	0.15	19.9m

[1] F. Gao et al., "Online safe trajectory generation for quadrotors using fast marching method and bernstein basis polynomial," ICRA, 2018

# Why hard?

- Time enters optimization nonlinearly
- Time is refined by gradient descent, but gradient is hard to compute.

# Formulation

For a flight corridor with  $n$  segments, use a piecewise Bézier curve of order  $d$ :

$\mathbf{c} \in R^{3n(d+1)}$ : control points of the curve

$\mathbf{y} \in R_{++}^n$ : time allocation

$$\text{minimize } J = \underbrace{\mathbf{c}^T P(\mathbf{y}) \mathbf{c}}_{\text{Jerk}} + w \underbrace{\mathbf{1}^T \mathbf{y}}_{\text{Traversal time}}$$

Quadratic in  $\mathbf{c}$   
Nonlinear in  $\mathbf{y}$

$$\text{subject to } G(\mathbf{y})\mathbf{c} \leq h$$

Trajectory stays in flight corridor  
Velocity/acceleration stay in the bound

$$L(\mathbf{y})\mathbf{c} = m$$

$C^2$ continuity at knot points  
Trajectory starts/ends at initial/final state

$$A\mathbf{y} \leq b, C\mathbf{y} = d$$

Fixed traversal time (optional),  
Time is positive

# Bilevel Formulation

$$\text{minimize } J = \mathbf{c}^T P(y) \mathbf{c} + w \mathbf{1}^T y$$

$$\begin{aligned} \text{subject to } & G(\mathbf{y}) \mathbf{c} \leq h \\ & L(\mathbf{y}) \mathbf{c} = m \\ & A\mathbf{y} \leq b, C\mathbf{y} = d \end{aligned}$$

$$\text{minimize } J = \mathbf{c}^T P(y) \mathbf{c} + w \mathbf{1}^T y$$

$$\begin{aligned} \text{subject to } & \mathbf{c} \in \operatorname{argmin} \{J: G(\mathbf{y}) \mathbf{c} \leq h, L(\mathbf{y}) \mathbf{c} = m\} \\ & A\mathbf{y} \leq b, C\mathbf{y} = d \end{aligned}$$

We use constrained gradient descent:

$$\mathbf{y} = \mathbf{y} - \alpha \operatorname{proj}_{A,C}(\nabla_{\mathbf{y}} J^*(\mathbf{y}))$$

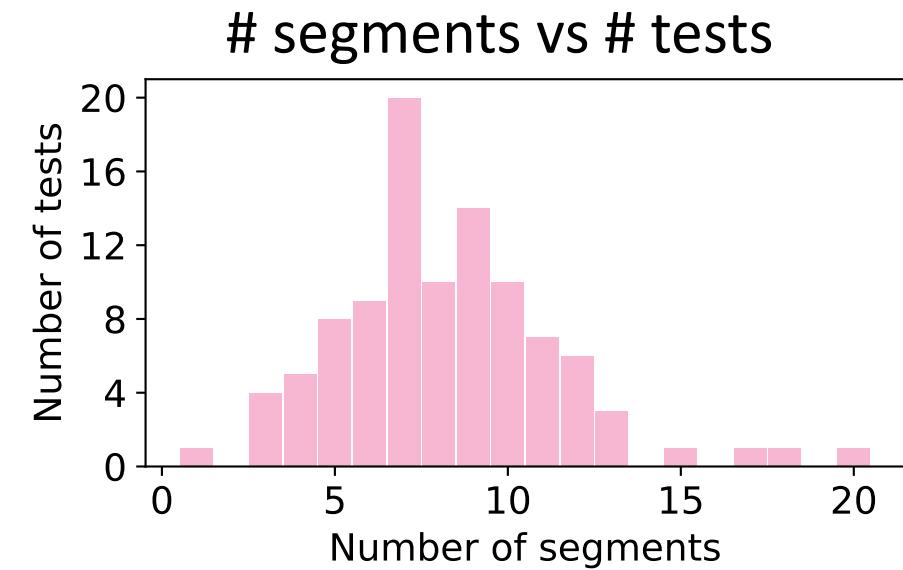

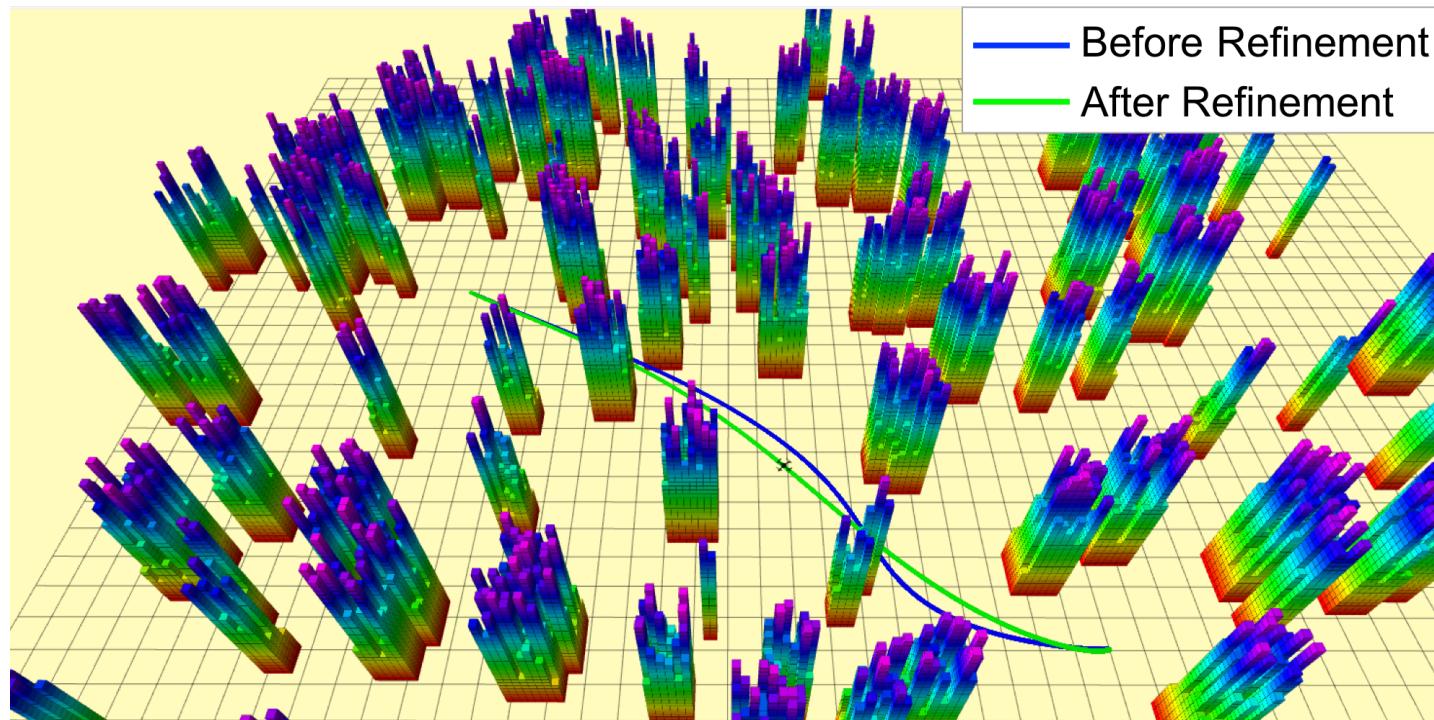

Gradient computation (from sensitivity analysis of parametric NLPs):

$$\nabla_{\mathbf{y}} J^*(\mathbf{y}) = \nabla_{\mathbf{y}} J + \lambda^T \nabla_{\mathbf{y}}(G(\mathbf{y}) \mathbf{c} - h) + \nu^T \nabla_{\mathbf{y}}(L(\mathbf{y}) \mathbf{c} - m)$$

$\lambda, \nu$ : Lagrange multipliers, which can be obtained “for free” by solving the QP

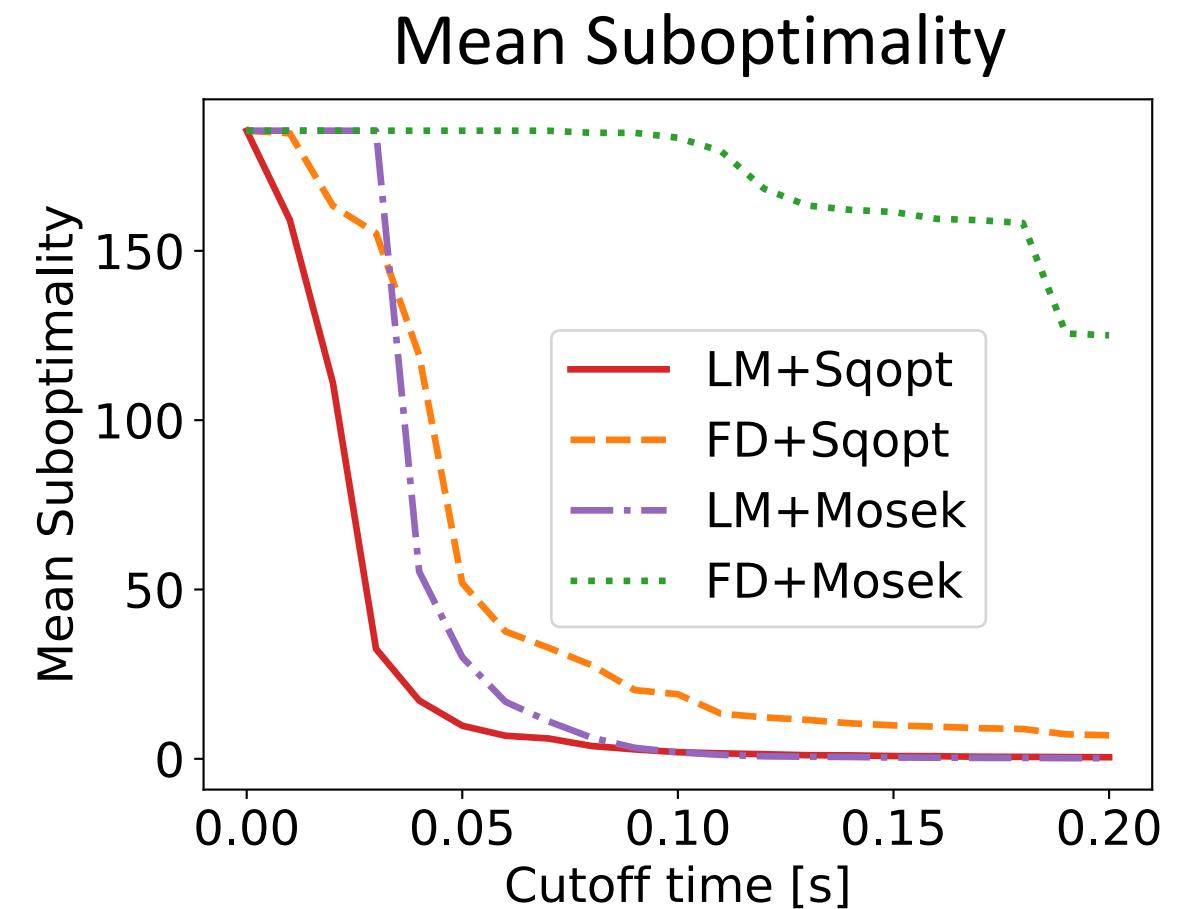

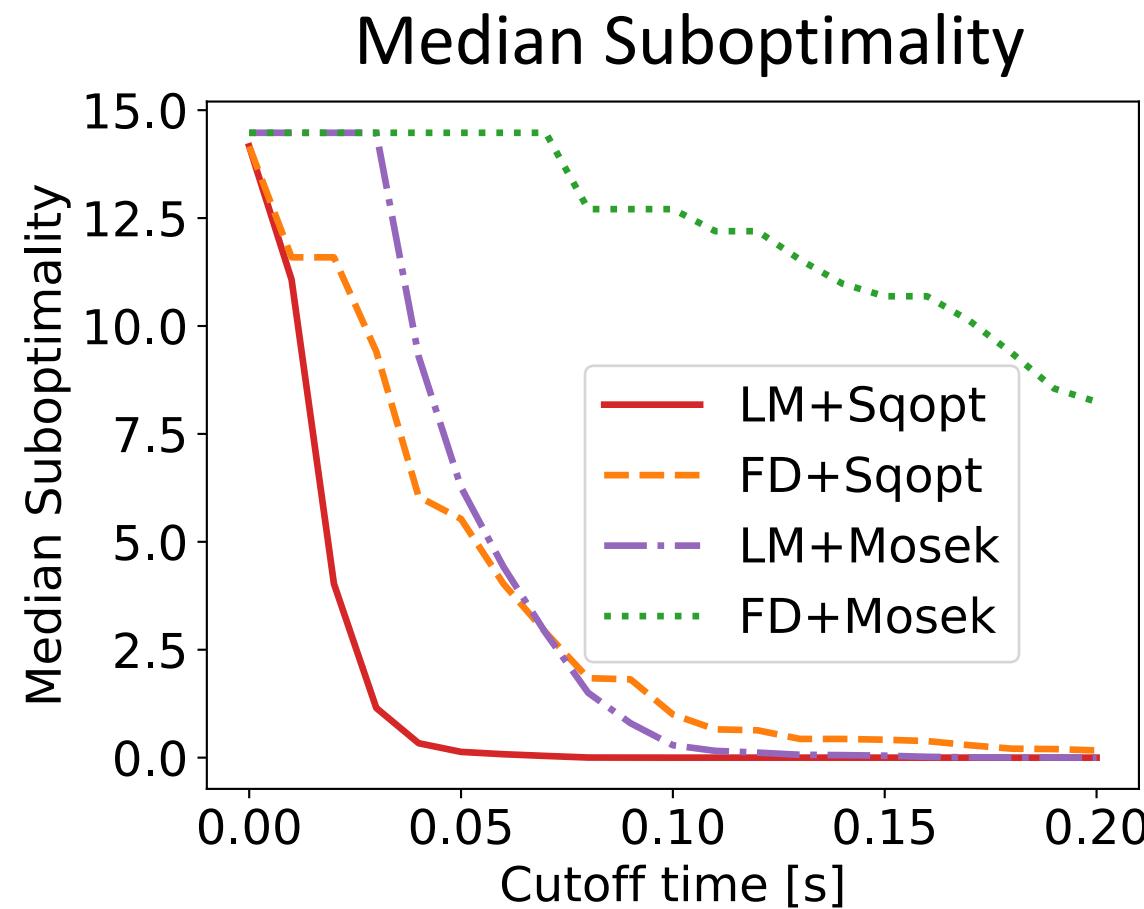

# Numerical experiments: real-time performance

- 100 tests: Random environment + random start/goal, fixed  $T$ ,  $w = 0$ .
- We solve  $c, y$  to optimal.

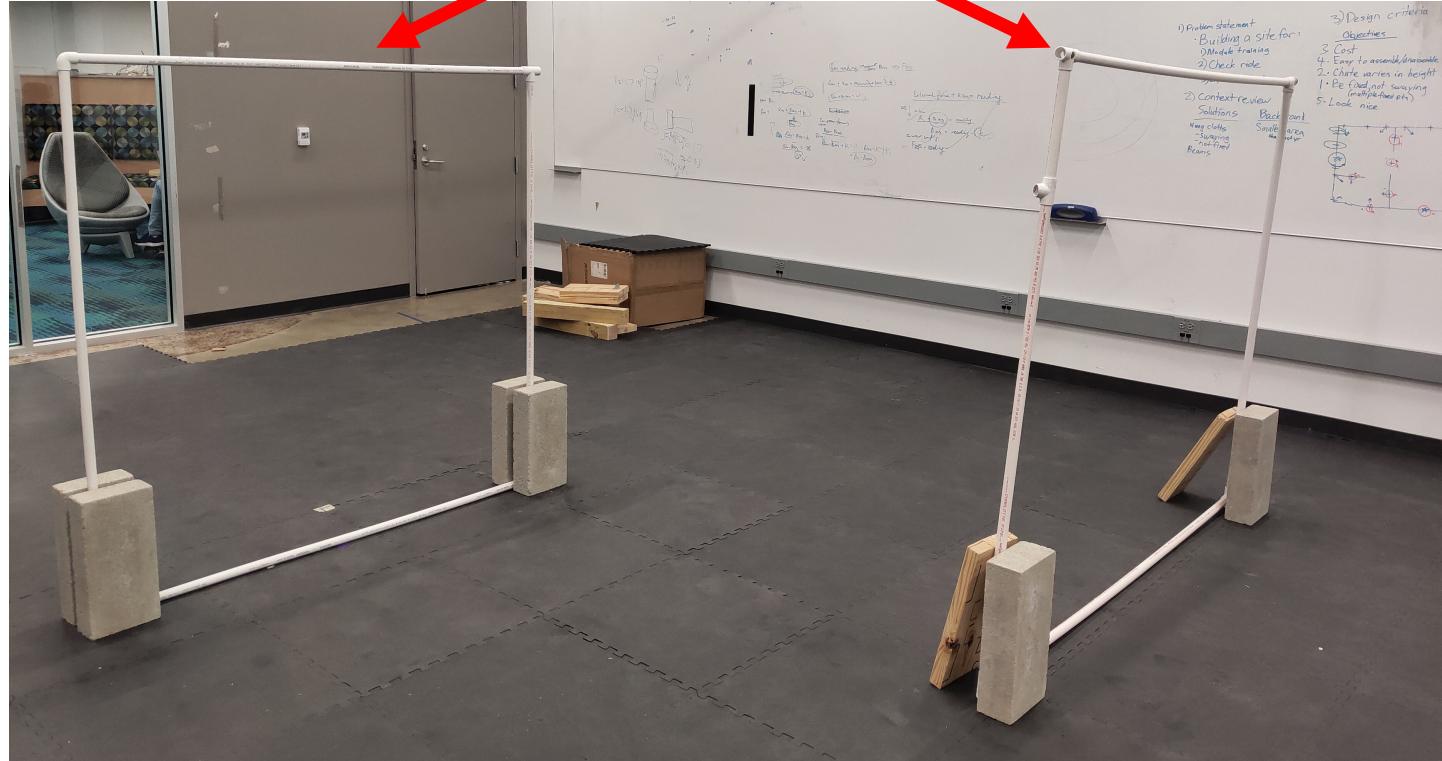

# Numerical experiments: real-time performance

- Our method (LM) vs finite difference (FD)
- 2 QP solvers are used: Sqopt (active-set), Mosek (interior-point)

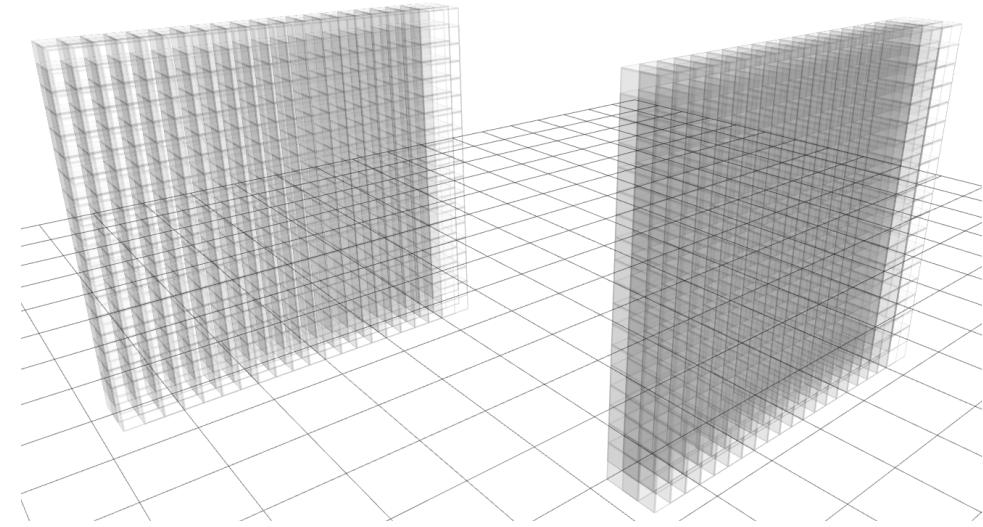

# Physical Experiment Setup

Frames treated as walls

Physical layout

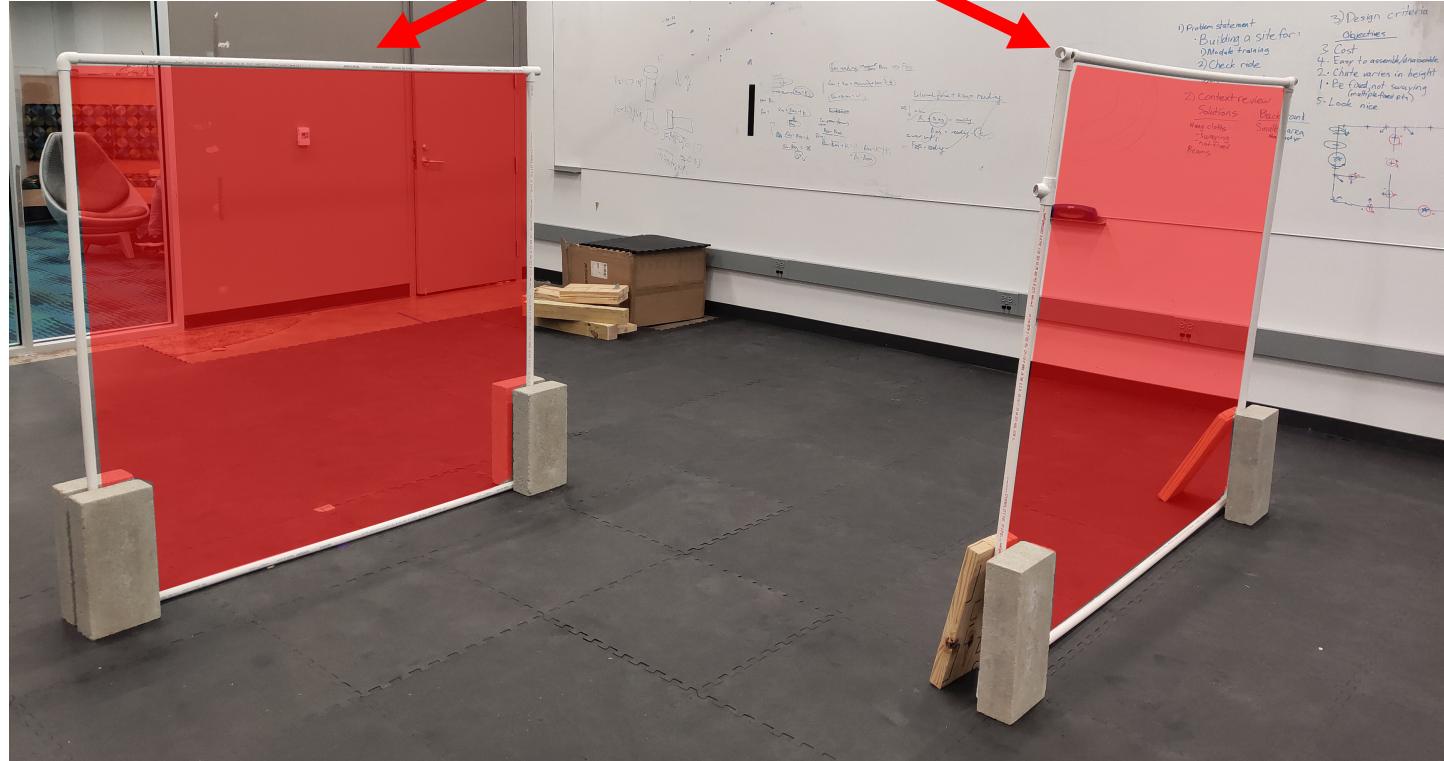

Rviz visualization

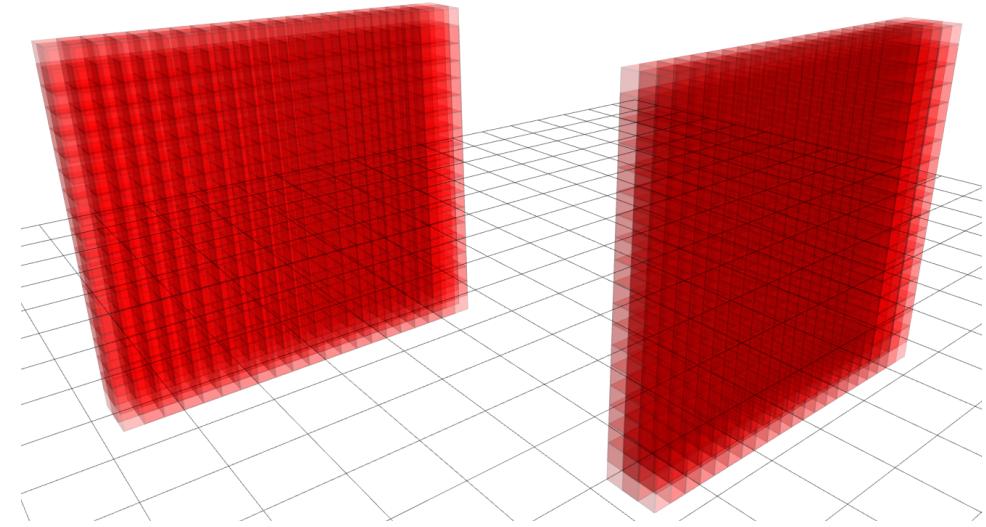

We use the Crazyflie 2.1

# Physical Experiment Setup

Frames treated as walls

Physical layout

Rviz visualization

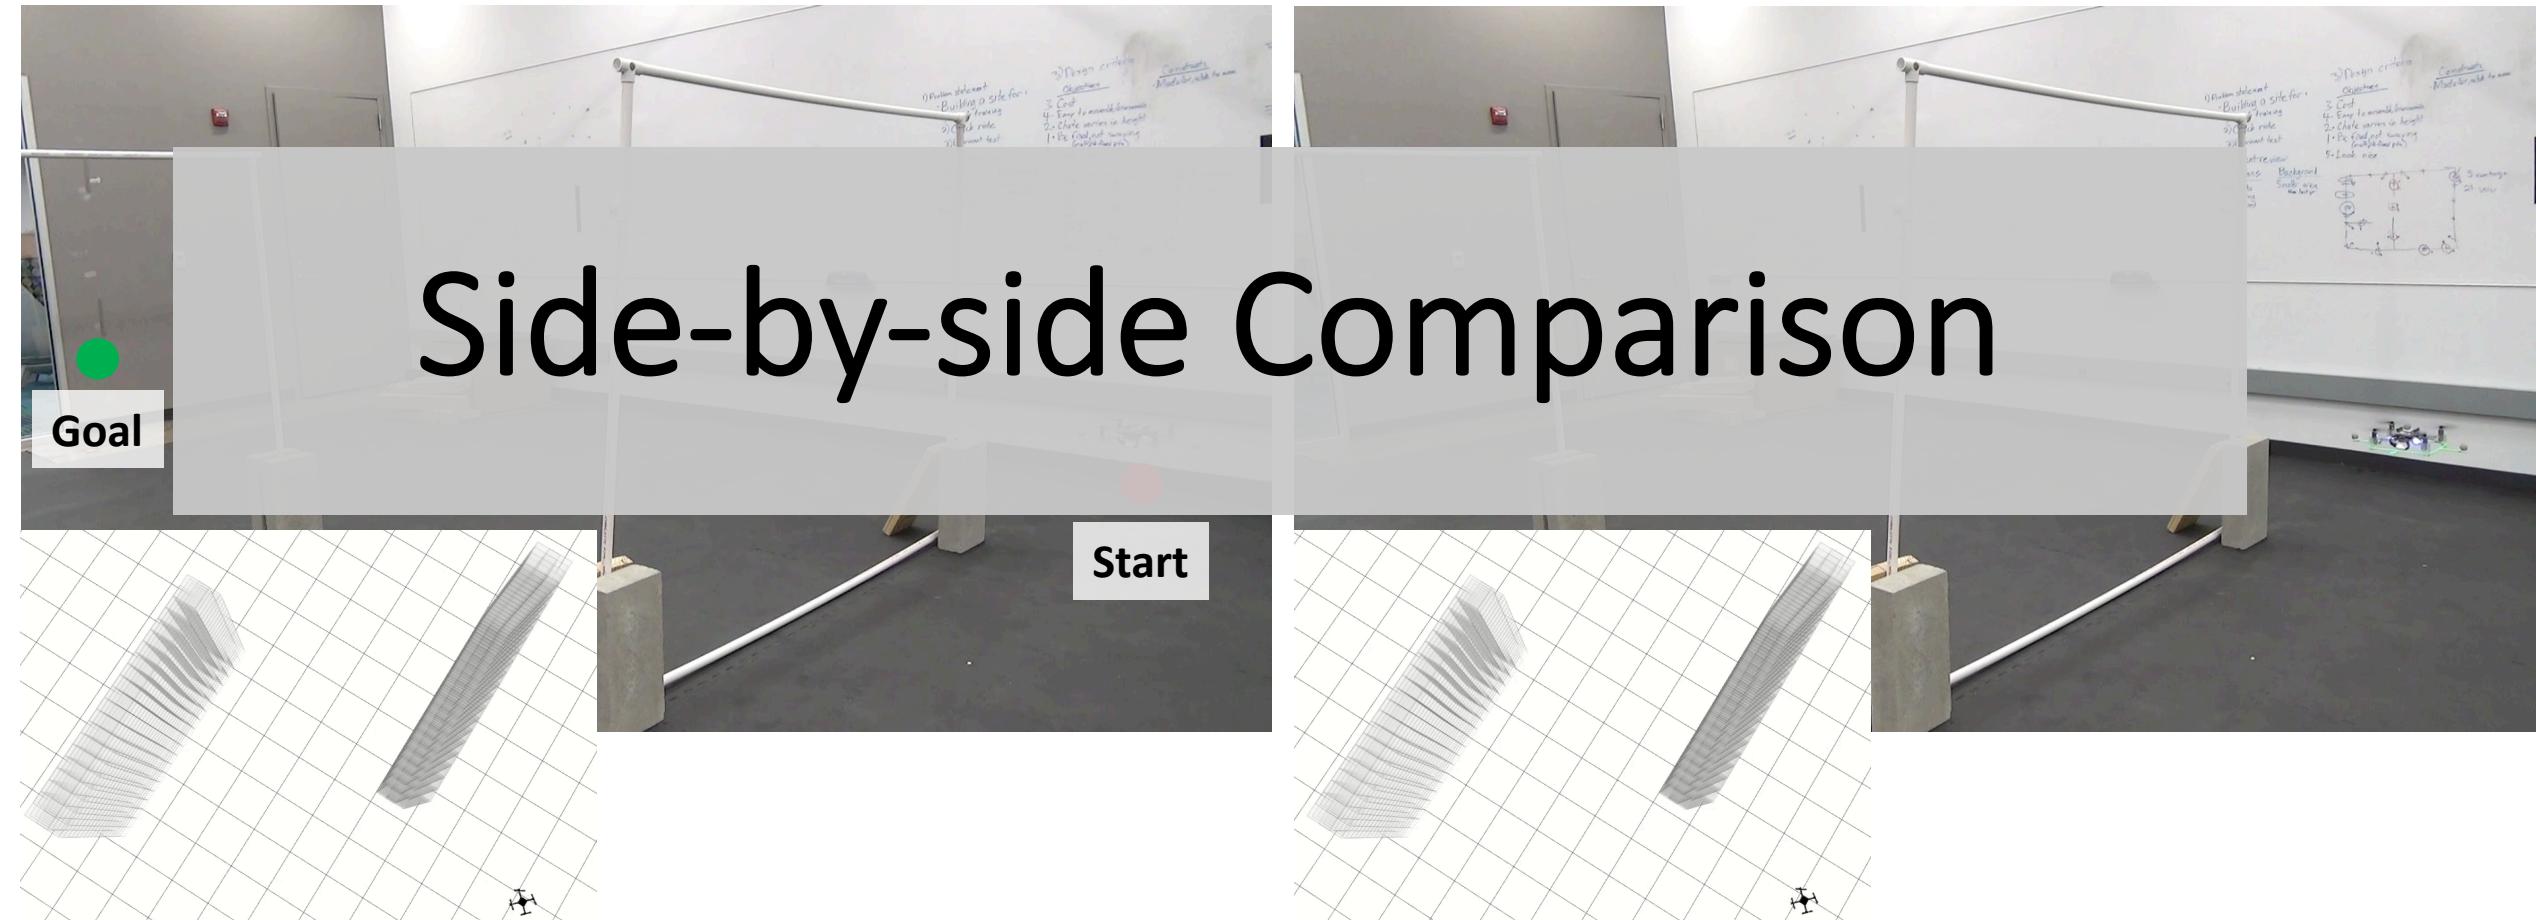

We use the Crazyflie 2.1

# Experiment 1

Our method plans a faster trajectory than state-of-the-art<sup>[1]</sup> with the same jerk

Gao et al. <sup>[1]</sup>,  $T = 5.32\text{s}$ , Jerk=39

Ours,  $T = 4.36\text{s}$ , Jerk=39

# Experiment 2

Our method can control aggressiveness using time penalty  $w$  (Plan time  $\sim 10$  ms)

$$w = 10, T = 5.60\text{s}, \text{Jerk} = 11.2$$

$$w = 20, T = 4.96\text{s}, \text{Jerk} = 19.9$$

## Side-by-side Comparison

$$w = 40, T = 4.42\text{s}, \text{Jerk} = 36.1$$

$$w = 80, T = 4.01\text{s}, \text{Jerk} = 64.7$$

# Experiment 3

Tracking a dynamic goal

Target

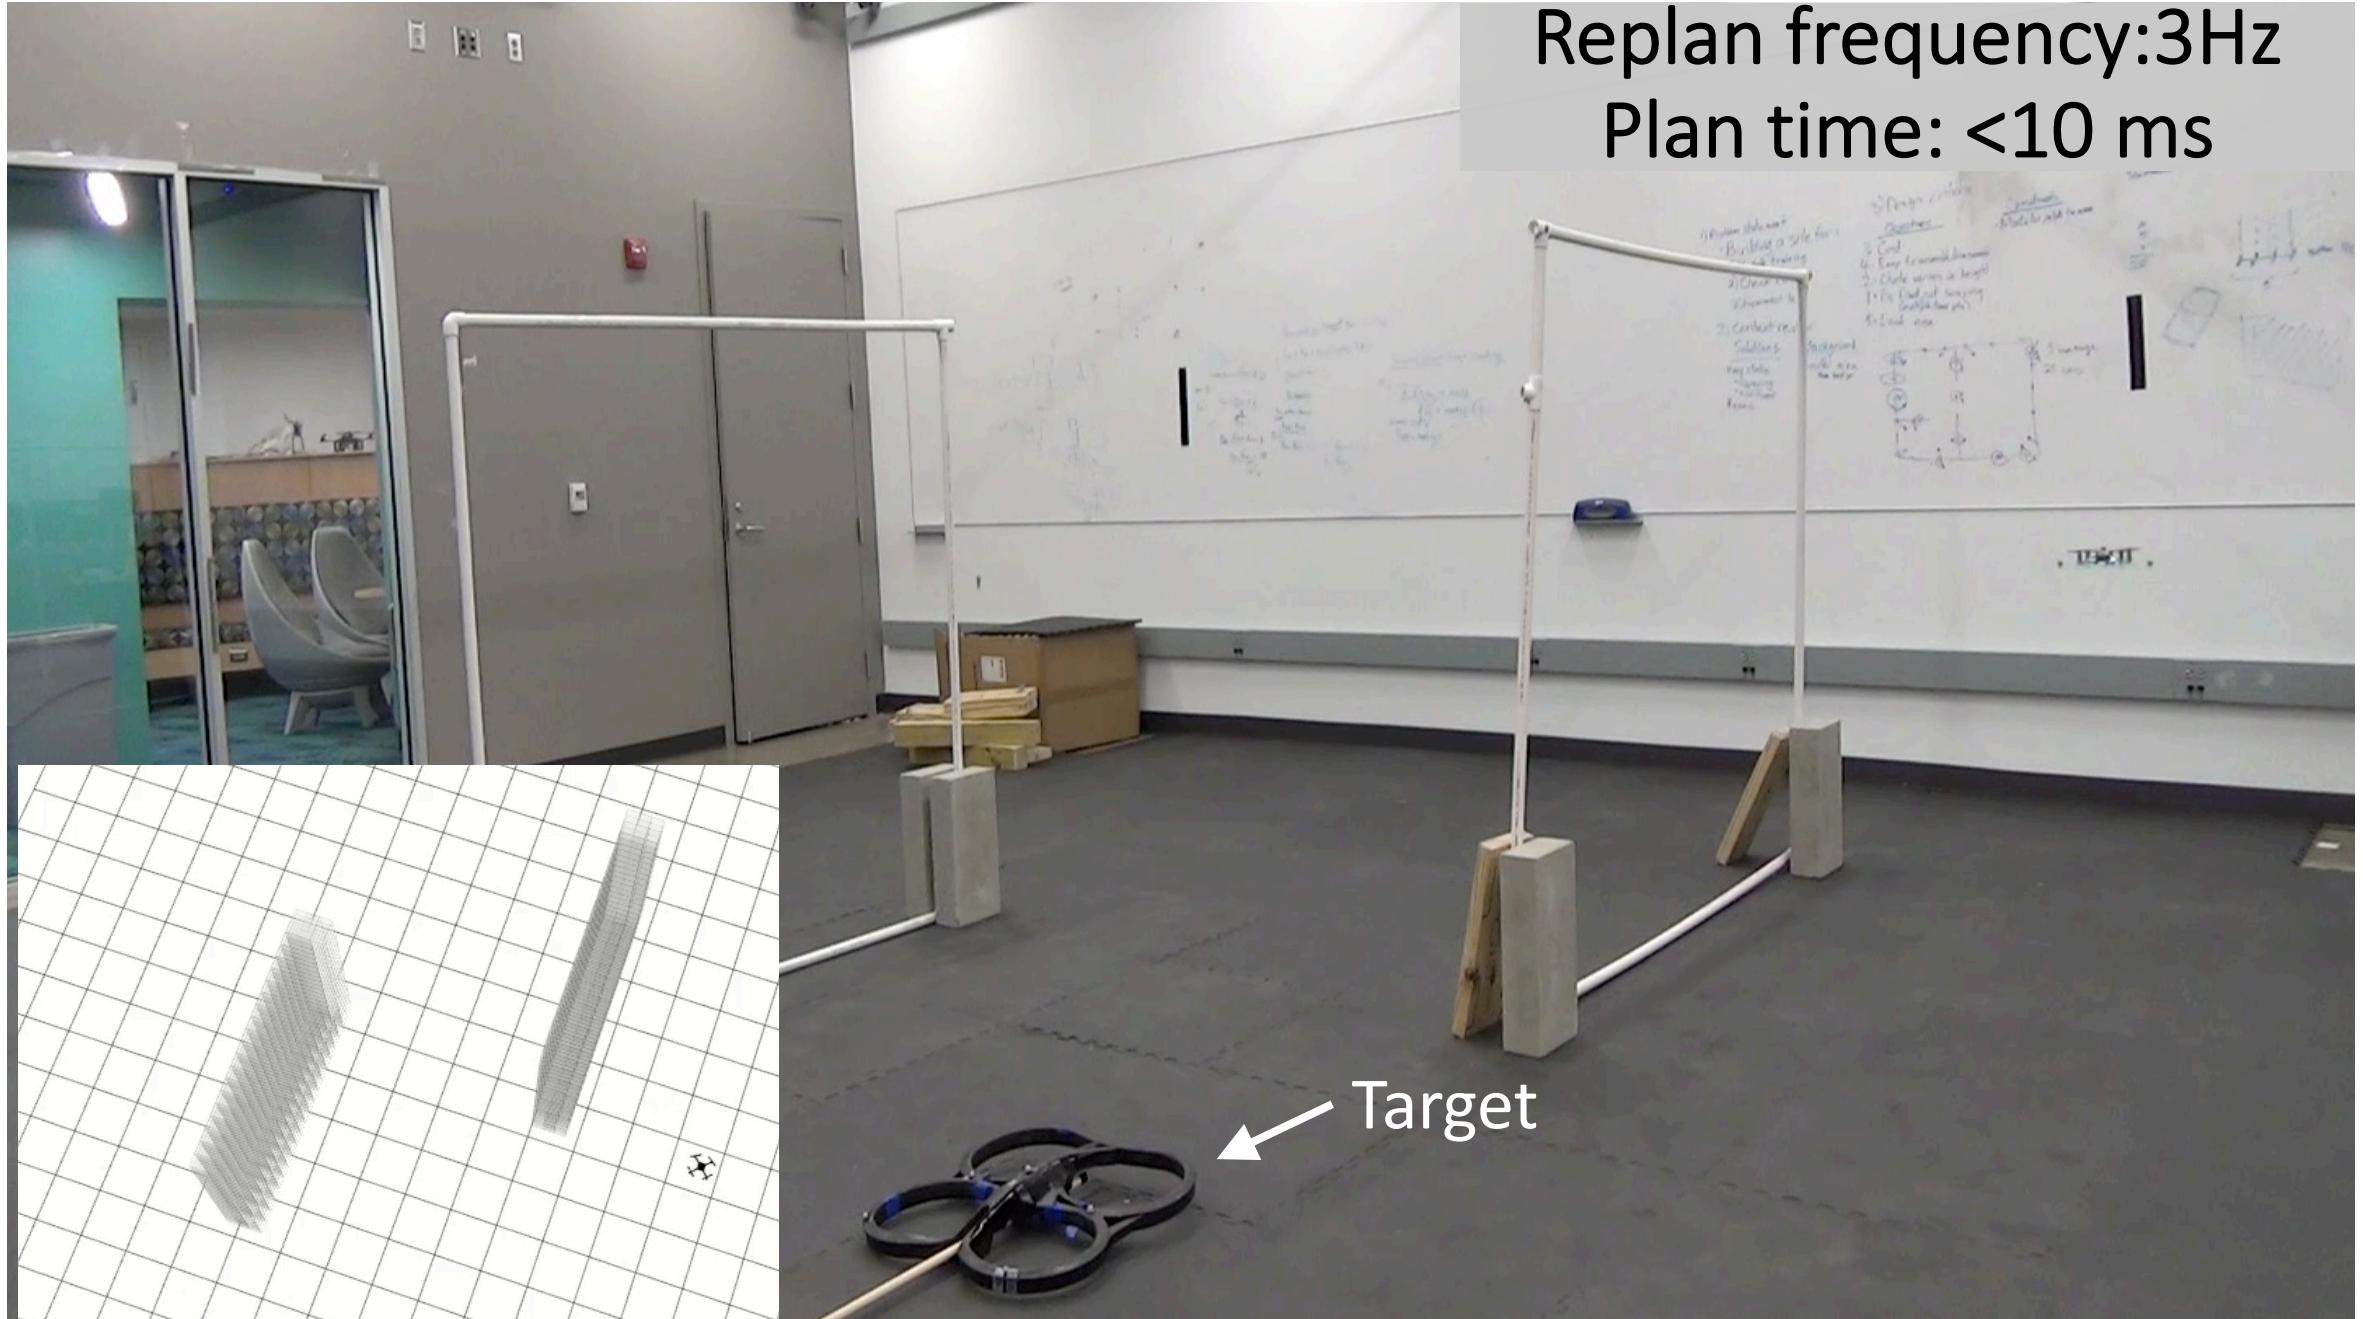

*Moved by human*

Quadrrotor

*Goal is 0.5m above the target*

Replan frequency: 3Hz  
Plan time: <10 ms

Thank you
